General Analysis of a Point Dislocation

1. Double-couple force equivalent
2. Moment magnitude $M_w$
3. The seismic moment tensor

Force Equivalent for a Buried Fault

Body force equivalent to the displacement discontinuity shown in the figure below (repeated):

\[
f_p(\eta, \tau) = - \int \int_\Sigma \left[ u_1(\xi, \tau) \right] c_{13pq} \frac{\partial}{\partial \eta_q} \delta(\eta - \xi) \, d\xi_1 \, d\xi_2
\]

In isotropic heterogeneous media, from

\[
c_{ijkl} = \lambda \delta_{ij} \delta_{kl} + \mu (\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk})
\]

we find that all \( c_{13pq} \) vanish except \( c_{1313} = c_{1331} = \mu \). Hence the body-force equivalent distribution over \( \Sigma \) becomes:

\[
f_1(\eta, \tau) = - \int \int_\Sigma \mu(\xi) \left[ u_1(\xi, \tau) \right] \delta(\eta_1 - \xi_1) \delta(\eta_2 - \xi_2) \frac{\partial}{\partial \eta_3} \delta(\eta_3) \, d\xi_1 \, d\xi_2
\]

\[
f_2(\eta, \tau) = 0,
\]

\[
f_3(\eta, \tau) = - \int \int_\Sigma \mu \left[ u_1 \right] \frac{\partial}{\partial \eta_1} \delta(\eta_1 - \xi_1) \delta(\eta_2 - \xi_2) \delta(\eta_3) \, d\xi_1 \, d\xi_2.
\]
Force Equivalent for a Buried Fault

The complete body-force equivalent to fault slip consists of two parts with both canceling moment and net force:

1. A single couple \((f_1)\) made up of forces pointing in the fault slip direction, and
2. A distribution of a fault-normal single force over \(\Sigma\) \((f_3)\) with total moment cancelling the one due to \(f_1\).

The absolute value of the total moment associated with each contribution is equal to \(\mu \bar{u} A\).

At great distance from the fault, wavelengths of seismic waves are much greater than the linear dimension of \(\Sigma\), and their periods much longer than the source duration. The slip thus becomes localized in space and time \(\bar{u} A \delta(\xi_1) \delta(\xi_2) H(\tau)\) and then:

\[
\begin{align*}
\mathbf{f}_1(\eta, \tau) &= -M_0 \delta(\eta_1) \delta(\eta_2) \frac{\partial}{\partial \eta_3} \delta(\eta_3) H(\tau) \\
\mathbf{f}_3(\eta, \tau) &= -M_0 \frac{\partial}{\partial \eta_1} \delta(\eta_1) \delta(\eta_2) \delta(\eta_3) H(\tau)
\end{align*}
\]

where \(M_0\) is called the seismic moment:

\[
M_0 = \mu \bar{u} A = \mu \times \text{average slip} \times \text{fault area}.
\]
Moment Magnitude $M_w$

The total moment magnitude due to each part of the body-force equivalent for a point dislocation is called the seismic moment $M_0$:

$$M_0 = \mu \bar{u} A = \mu \times \text{average slip} \times \text{fault area}.$$ 

This quantity is a measure of the source strength and does not depend on the kind of seismic wave used to determine it.

Earthquakes magnitude has been determined empirically by means of specific waves amplitudes, such as body ($M_b$) and surface waves ($M_s$).

Kanamori (1977) introduced the Moment Magnitude $M_w$, which is based on $M_0$ and approximately equal to $M_s$ in the frequency range where the surface waves spectrum is not saturated:

$$M_w = \left( \frac{\log M_0}{1.5} \right) - 10.73.$$
The Seismic Moment Tensor

The seismic moment tensor is a quantity that depends on the fault strength and orientation. It is a generalized description of body-force equivalents for seismic sources consisting of force couples and dipoles.

We start from the following representation of displacements in terms of the slip on the fault by introducing the convolution symbol (repeated):

\[
\mathbf{u}_n(\mathbf{x}, t) = \iiint_{\Sigma} \left[ u_i \right] \nu_j c_{ijpq} \ast \frac{\partial}{\partial \xi_q} G_{np} \, d\Sigma.
\]

Note that, if functions \( f(t) \) and \( g(t) \) are zero for \( t < 0 \), then

\[
f \ast g = \int_0^t f(\tau)g(t - \tau) \, d\tau = \int_0^t f(t - \tau)g(\tau) \, d\tau = \int_{-\infty}^\infty f(\tau)g(t - \tau) \, d\tau
\]

From the representation of displacement as a function of the time varying force \( f_p \) that originate it

\[
\mathbf{u}_n(\mathbf{x}, t) = \int_{-\infty}^{\infty} d\tau \iiint_{V} f_p(\eta, \tau)G_{np}(\mathbf{x}, t - \tau; \eta, 0) \, dV(\eta)
\]

if \( f_p \) is applied in the p-direction at the fault point \( \xi \), then the n-component of displacement at \((\mathbf{x},t)\) is given by the convolution

\[
F_p \ast G_{np}
\]
The Seismic Moment Tensor

For a displacement discontinuity (i.e. fault slip or opening), the representation formula depends on the spatial derivatives of the Green function $G_{np}$

$$u_n(x, t) = \int \int_\Sigma [u_i] v_j c_{ijpq} \frac{\partial}{\partial \xi_q} G_{np} \, d\Sigma.$$ 

that, as previously demonstrated, correspond to a single force couple each, with arm in the $\xi_q$-direction. The sum over index $q$ tells us that each displacement component at $x$ is the contribution of a sum of force couples and dipoles distributed over $\Sigma$.

Since the integrand is the $n$-component of the displacement at $x$ due to couples at $\xi$, it follows that $[u_i] v_j c_{ijpq}$ is the strength of the $(q,p)$ couple, which has units of moment per unit area. The moment contribution of each fault unit area is the strength weighted by the infinitesimal surface area $d\Sigma$. 
The Seismic Moment Tensor

We thus define the time-dependent components of the moment density tensor to be:

\[
m_{pq} = \left[ u_i \right] v_j c_{ijpq}
\]

In terms of this tensor, the representation theorem for displacement at \( x \) due to general displacement discontinuity \([u(\xi, \tau)]\) across \( \Sigma \) is:

\[
u_n(x, t) = \iiint_{\Sigma} m_{pq} * G_{npq} d\Sigma.
\]

In an isotropic medium with displacement discontinuity without fault opening (i.e. slip or shear dislocation), the moment density tensor becomes

\[
m_{pq} = \mu \left( v_p \left[ u_q \right] + v_q \left[ u_p \right] \right).
\]

If \( \Sigma \) lies in the \( \xi_3 = 0 \) plane with slip only in the \( \xi_3 \)-direction (figure), the moment density consists of the force double-couple:

\[
m = \begin{pmatrix}
0 & 0 & \mu \left[ u_1(\xi, \tau) \right] \\
0 & 0 & 0 \\
\mu \left[ u_1(\xi, \tau) \right] & 0 & 0
\end{pmatrix},
\]
The Seismic Moment Tensor

If $\Sigma$ lies in the $\xi_3 = 0$ plane and $[u3]$ is the only nonzero displacement component (figure), the moment density consists of three force dipoles:

$$m = \begin{pmatrix} \lambda [u_3(\xi, \tau)] & 0 & 0 \\ 0 & \lambda [u_3(\xi, \tau)] & 0 \\ 0 & 0 & (\lambda + 2\mu) [u_3(\xi, \tau)] \end{pmatrix}$$

In observational seismology we often analyze seismic wave with very long periods so for which the whole of $\Sigma$ is effectively a point source. So by integrating the contribution of every single fault unit area, the representation of displacement reads

$$u_n(\mathbf{x}, t) = M_{pq} \ast G_{np,q}$$

where the moment tensor, $M_{pq}$, is thus given by

$$M_{pq} = \int \int_{\Sigma} m_{pq} \ d\Sigma = \int \int_{\Sigma} [u_i] \nu_j \epsilon_{ijpq} \ d\Sigma,$$
The Seismic Moment Tensor

The seismic moment tensor may be expressed as

\[ M_{kj} = \mu A (D_k v_j + D_j v_k), \]

where A is the total fault area and \( D_i \) the slip vector. Its components are:

\[
\begin{align*}
M_{11} &= -M_0(\sin \delta \cos \lambda \sin 2\phi_f \\
&\quad + \sin 2\delta \sin \lambda \sin^2 \phi_f) \\
M_{22} &= M_0(\sin \delta \cos \lambda \sin 2\phi_f \\
&\quad - \sin 2\delta \sin \lambda \cos^2 \phi_f) \\
M_{33} &= M_0(\sin 2\delta \sin \lambda) = -(M_{11} + M_{22}) \\
M_{12} &= M_0(\sin \delta \cos \lambda \cos 2\phi_f \\
&\quad + \frac{1}{2} \sin 2\delta \sin \lambda \sin 2\phi_f) \\
M_{13} &= -M_0(\cos \delta \cos \lambda \cos \phi_f \\
&\quad + \cos 2\delta \sin \lambda \sin \phi_f) \\
M_{23} &= -M_0(\cos \delta \cos \lambda \sin \phi_f \\
&\quad - \cos 2\delta \sin \lambda \cos \phi_f).
\end{align*}
\]

Since the moment tensor is symmetric, it may be diagonalized by rotating it into a principal-axis system.

The rotated tensor components correspond to the eigenvalues of the moment tensor, and the associated eigenvectors give the directions of the tensional (T), intermediate (B) and compressional (P) stress axis.
The Seismic Moment Tensor

The diagonalized moment tensor may be decomposed into two separate tensors, namely the isotropic and deviatoric moment tensors, so that

\[
M = \begin{bmatrix}
M_1 & 0 & 0 \\
0 & M_2 & 0 \\
0 & 0 & M_3
\end{bmatrix} = \frac{1}{3} \begin{bmatrix}
\text{tr}(M) & 0 & 0 \\
0 & \text{tr}(M) & 0 \\
0 & 0 & \text{tr}(M)
\end{bmatrix} + \begin{bmatrix}
M_1^1 & 0 & 0 \\
0 & M_2^1 & 0 \\
0 & 0 & M_3^1
\end{bmatrix},
\]

Where \(\text{tr}(M) = M_1 + M_2 + M_3\) is the trace of \(M\), and the remaining terms \(M_i\) are the deviatoric eigenvalues of \(M\).

The isotropic moment tensor components reveal the volume change of the medium due to either an explosion or implosion. Most shearing sources appear to have little isotropic component so often, when determining their moment tensor, seismologists assume that \(\text{tr}(M) = 0\).

The deviatoric moment tensor may be decomposed in different ways: three vector dipoles, three compensated linear vector dipoles (CLVDs), a double couple and a CLVD, etc.
